FUNDAMENTALS IN AI ML

PROJECT REPORT

(Voice Assistant using Python)

Submitted By: Adarsh Patel

Registration Number:25BAI10252

Course: B.Tech CSE (AI/ML)

School :SCAI

1. Introduction

With the rapid advancement of Artificial Intelligence, voice-based systems have become an important part of human-computer interaction. Virtual assistants like Siri, Alexa, and Google Assistant have made it easier for users to interact with machines using natural language.

This project presents a basic voice assistant developed using Python, which can understand voice commands and respond accordingly. It demonstrates how speech recognition and text-to-speech technologies can be combined to create an interactive system.

---

2. Objectives

The main objectives of this project are:

- **To develop a simple voice-controlled assistant using Python**
- **To understand the working of speech recognition systems**
- **To implement text-to-speech conversion**
- **To perform basic tasks like telling time and searching Wikipedia**
- **To improve user interaction with computers using voice**

---

3. Problem Statement

Traditional computer interaction relies heavily on keyboards and screens, which may not always be convenient. There is a need for more natural and efficient ways to communicate with systems.

This project aims to solve this problem by creating a voice-based assistant that allows users to perform tasks through spoken commands.

---

4. Methodology

The project follows a step-by-step approach:

1. **Capture audio input using a microphone**
2. **Convert speech into text using a speech recognition API**
3. **Process the command using conditional logic**
4. **Perform the required task**
5. **Convert the output text into speech**

This creates a continuous interaction loop between the user and the system.

---

5. Tools and Technologies Used

- **Programming Language: Python**
- **Libraries Used:**
  - **speech_recognition – for converting speech to text**
  - **pyttsx3 – for text-to-speech conversion**
  - **wikipedia – for fetching information**
  - **datetime – for time-related functions**

---

6. System Architecture

The system consists of the following components:

- **Input Module: Captures voice input using microphone**
- **Processing Module: Converts speech to text and interprets commands**
- **Execution Module: Performs tasks like time retrieval or Wikipedia search**
- **Output Module: Converts response into speech**

---

7. Implementation Details

The project is implemented using modular functions:

- **speak(text) → Converts text to speech**
- **recognize_speech() → Captures and processes voice input**
- **get_time() → Retrieves and speaks current time**
- **search_wikipedia(query) → Fetches summary from Wikipedia**
- **process_command(command) → Handles logic for different commands**
- **start_voice_assistant() → Runs the assistant continuously**

The assistant listens for commands in a loop and executes tasks accordingly.

---

8. Features

- **Voice command recognition**
- **Audio response system**
- **Real-time time display**
- **Wikipedia search functionality**
- **Exit/stop command**

---

9. Results

The voice assistant successfully performs:

- **Accurate speech recognition (with internet connection)**
- **Clear audio responses**
- **Efficient execution of commands**

The system demonstrates smooth interaction between user and machine.

---

10. Limitations

- **Requires internet for speech recognition**
- **Limited command understanding**
- **No graphical user interface**
- **Accuracy depends on microphone quality and noise**

---

11. Future Scope

- **Integration with AI chatbot for intelligent responses**
- **Adding more commands (open apps, play music, etc.)**
- **GUI-based interface**
- **Offline speech recognition**
- **Multi-language support**

---

12. Conclusion

This project successfully demonstrates the implementation of a basic voice assistant using Python. It highlights how AI concepts like speech recognition and natural language interaction can be applied in real-world applications.

The system provides a foundation for building more advanced and intelligent voice-based systems.
